

Software to install on your computer before the SEED program begins

1. **Anaconda Python:** Install the latest version of [Anaconda Navigator from their website](#). This is free software for both Mac and Windows. It will have an icon with a green circle. Please verify that you can open this app (by double clicking on the icon) after the installation is complete.
2. **Command-line Terminal:** For Mac users, no installation is needed; you will use your Terminal application. Please ensure that you have this application (found in Application / Utilities or via the search utility) and that you can open it. For Windows users, please [install git bash from their website](#). After the installation is complete, please open the git bash terminal (via double clicking the icon) to verify that it works.
3. **Git:** For both Mac and Windows users, please verify that Git is available by launching your command-line terminal application (see step 2. above) and typing `git --version` in the terminal and then the enter (or return) key. If you see a version number printed below your command, Git is available, and you can move onto step 4. If you do not see a version number, you will need to install Git manually, following these steps:
 - o **macOS:** Xcode command-line tools ship a Git binary with them. To install Xcode command-line tools, open the Terminal application and type `xcode-select -install` and then the enter (or return) key.
 - o **Windows:** In your terminal, type: `winget install --id Git.Git -e --source winget` (all one line) and then the enter (or return) key.
 - o **Verify the installation (Windows and MacOS):** After you have installed Git, close your terminal. Then open a fresh command-line terminal and type `git --version` again. You should see a version number this time around.
4. **GitHub:** Please create an account for yourself on [the GitHub website](#) if you don't have one already.
5. **Text editor:** You will need a text editor that is not Microsoft Word (or any other app with internal formatting) to write and edit code. If you prefer not to install any additional applications, Windows users could use Notepad and MacOS could use TextEdit (both of which should be installed by default), or you could use a text editor that comes with Anaconda. I personally prefer [VS Code](#) (which is free, available for both Windows and Mac, very flexible, and is widely used for code development). I encourage you to test a few options and decide what works best for you.
